Föreläsning 5: Cryptography as a tool

Guilherme B. Xavier

“Cryptography” is a Greek word that means “hidden writing”

Used to hide message from someone, and to also protect the integrity of a message

“Cryptography” is a Greek word that means “hidden writing”

Used to hide message from someone, and to also protect the integrity of a message

Cryptography is today used in other settings too

There are situations where participants don't really trust each other, but a third party

Cryptography is today used in other settings too

There are situations where the authorities want access to the communication channel

Cryptography

- A security *tool*, not a general solution
- Cryptography usually converts a communication security problem into a key management problem
- So now you must take care of the key security problem, which becomes a problem of computer security

Images of cryptographic tasks

Hide information securely,
opens with identical keys
(symmetric key cryptography)

Make something visible,
but hinder changes
(signatures)

Everyone can hide information, opens
with private key
(asymmetric key cryptography)

Enables simple checking of data
(hash functions)

Terminology

- The *plaintext* is the information in its normal form
- The *ciphertext* or *cryptogram* is the transformed plaintext
- The secret parameter for the encryption (known only to the sender and intended recipients) is called the *key*
- The key decides how the transformation is done

Kerckhoff's principle

- A cryptosystem should be secure even if everything about the system, except the key, is public knowledge.

Classical crypto example: Caesar cipher

- Exchange every plaintext letter into the letter x positions further on in the alphabet
- The key is the letter that A is transformed into

Classical crypto example: Caesar cipher

- Exchange every plaintext letter into the letter x positions further on in the alphabet
- The key is the letter that A is transformed into

The diagram illustrates a Caesar cipher with a shift of 2 positions. It features two rows of the alphabet. The top row is 'A B C D E F G H I J K L M N O P Q R S T U V W X Y Z'. The bottom row is 'C D E F G H I J K L M N O P Q R S T U V W X Y Z A B'. A green circle highlights the letter 'E' in the top row, and a red circle highlights the letter 'G' in the bottom row. A green line connects 'E' to 'G', representing the transformation of the letter 'E'. A red line connects 'G' in the top row to 'I' in the bottom row, representing the transformation of the letter 'G'. Below the top row, the text 'Hello world' is written, with a green line connecting the 'H' to the 'H' in the bottom row. Below the bottom row, the text 'Jg' is written, with a red line connecting the 'J' in the top row to the 'J' in the bottom row.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

C D E F G H I J K L M N O P Q R S T U V W X Y Z A B

Hello world

Jg

Classical crypto example: Caesar cipher

- Exchange every plaintext letter into the letter x positions further on in the alphabet
- The key is the letter that A is transformed into

Classical crypto example: Caesar cipher

- Exchange every plaintext letter into the letter x positions further on in the alphabet
- The key is the letter that A is transformed into

A B C **D** E F G H I J K L M N O P Q R S T U V W X Y Z
C D E **F** G H I J K L M N O P Q R S T U V W X Y Z A B

 Hello world Jgnnq yqtnf

Breaking Caesar, example

- Cryptogram: lcnnkc qopkc fkxkuc guv kp rctvgu swcgtwo wpcokpeqnwpv Dgnikcg...
- Try each key, stop trying for each key when the plaintext becomes impossible

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z
I	H	G	F	E	D	C	B	A	Z	Y	X	W	V	U	T	S	R	Q	P	O	N	M	L	K	J

n		l	k	j				f	e	d				z	y	x			u	t	s	r	p	o	
n		l		j				f	e					z	y				u	t		r	p	o	
k		i		g				u	t					w	v				j	q		o	m	d	
		a						i	h	f				c	n				x	w		g	s	r	
		o						g						a					v	u		u	q		
		m						h						b							s	t	r		
		n						c						w							o		m		
		i												o											
		a												r											
		d																							

Breaking Caesar, example

- Cryptogram: `lcnnkc qopkc fkxkuc guv kp rctvgu swcgtwo wpcokpeqnwpv Dgnikcg...`
- Try each key, stop trying for each key when the plaintext becomes impossible

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z
I	H	G	F	E	D	C	B	A	Z	Y	X	W	V	U	T	S	R	Q	P	O	N	M	L	K	J
c	b	a	z	y	x	w	v	u	t	s	r	q	p	o	n	m	l	k	j	i	h	g	f	e	d
n		l	k			h	g	f	e	d	c	b		z	y	x			u	t	s			p	o
n		l	j					f	e	d				z	y				u	t				p	o
k		i	g					c	b					w	v				r	a				m	l
		a																			o			e	d
		o																			g			s	r
		m																			u			q	p
		n																			s			r	
		i																			t			m	
		a																			o				
		d												o	r										

Only remaining possible key: C

Plaintext: Gallia est omnis
divisa in partes tres, quarum unam
incolunt Belgae, ...

Simple substitution

- Create a table of plaintext characters and their corresponding crypto characters
- Crypto characters can be just ordinary letters, but also anything else
- Each crypto character must occur only once in the table to enable unique decryption

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z
G	Z	E	J	D	Y	I	T	Q	A	U	M	B	W	R	F	C	X	H	N	S	L	O	K	P	V

Breaking simple substitution

- Every crypto letter will occur exactly as often as its plaintext counterpart occurs in plaintext.
- Every combination of crypto letters (digrams, trigrams etc.) will occur as often as the corresponding plaintext combinations.
- Count how often letters, bigrams and trigrams occur in the cryptogram, and try to identify the ones corresponding to common plaintext letters and common letter combinations.
- Fill in so that remaining gaps form words.

The letter distribution of English is uneven

- An even distribution would look like the above

The letter distribution of English is uneven

- An even distribution would look like the above
- But the single letter distribution of English is uneven

The letter distribution of English is uneven

- An even distribution would look like the above
- But the single letter distribution of Swedish is uneven

Cryptanalysis

The goal of cryptanalysis can be

- reveal the key
- decrypt (part of) cryptograms without the key
- encrypt (part of) plaintexts without the key

In order to break a cipher you could

- Try all possible keys (brute force, exhaustive search)
- Use plaintext alphabet statistics
- Use both single letter statistics, and digram, trigram, and word statistics
- Do calculations adjusted to the algorithm

Algorithm strength

- This is measured in the amount of work needed to break the cipher
- The comparison is with brute force
- For Caesar crypto, you need to check 26 keys, or just under 2^5 values
- For simple substitution you need to check $26!$ keys ($\approx 4 \times 10^{26}$), or just over 2^{88} values
- But with letter statistics this drops quickly

Key size

- There are 31536000 seconds in a year $\approx 2^{25}$
- If you can try one key every microsecond, you can find a 45 bit key in around one year ($10^6 \approx 2^{20}$)
- If you have 1000 such processors, you can find a 55 bit key in around one year
- With 1000 processors that try one key every nanosecond, the expected time to find a 128 bit key is more than 10^{18} years

Key length

Table 7.4: Security levels (symmetric equivalent)

Security (bits)	Protection	Comment
32	Real-time, individuals	Only auth. tag size
64	Very short-term, small org	Not for confidentiality in new systems
72	Short-term, medium org Medium-term, small org	
80	Very short-term, agencies Long-term, small org	Smallest general-purpose < 4 years protection (E.g., use of 2-key 3DES, < 2^{40} plaintext/ciphertexts)
96	Legacy standard level	2-key 3DES restricted to 10^6 plain-text/ciphertexts, ≈ 10 years protection
112	Medium-term protection	≈ 20 years protection (E.g., 3-key 3DES)
128	Long-term protection	Good, generic application-indep. Recommendation, ≈ 30 years
256	"Foreseeable future"	Good protection against quantum computers unless Shor's algorithm applies.

Strength of algorithms

- There is one perfectly secure algorithm: the One Time Pad, which needs a (random secret shared) key as long as the message
- Modern ciphers are immune to simple attacks
- Algorithm weakness is almost never a problem with approved algorithms today
- Badly chosen keys, bad key management, and bad implementations are the current problems

Algorithm types

There are three basic algorithm types

- Stream ciphers, very fast and suited for confidentiality, not data integrity
- Block ciphers, can be symmetric key which are fast, and asymmetric that are slower, both suited for confidentiality and integrity (with some precautions)
- One way functions, fast, only for data integrity

The perfect stream cipher: the One-time-pad

- Useful for sending secret data without preserved data integrity
- Use a long random bitsequence as key
- Add this to the plaintext to form the cryptogram
- Not practical: needs new random keys as long as the message

A practical stream cipher

- Use a long *pseudo*-random bitsequence as key, generated from a short seed (key) k and initial state s_0
- Add this to the plaintext to form the cryptogram
- Useful for sending secret data without preserved data integrity

A practical stream cipher

- Encrypts bit by bit, fits well with any cipher text length
- The sequence generator state sequence should be very long.

Proper randomness, and sharing it

- Generate a pseudorandom “key stream” from a seed, a “real key” much shorter than the full “key stream” added to the message
- Make the set of possible seeds, the real keys, so large that exhaustive search is impossible
- Eliminate shortcuts to finding this key from the “key stream”

Stream ciphers and message integrity

- Imagine you are able to intercept the bank transfer that puts your salary into your bank account, and that it is encrypted with a stream cipher, and not authenticated
- You know what your salary is, and in what position it is on the bank transfer:

```
... CR LF SPC SPC SPC SPC SPC SPC 3 0 0 0 0 CR LF ...  
... 13 10 32 32 32 32 32 32 51 48 48 48 48 13 10 ...
```

Stream ciphers and message integrity

- Imagine you are able to intercept the bank transfer that puts your salary into your bank account, and that it is encrypted with a stream cipher, and not authenticated
- You know what your salary is, and in what position it is on the bank transfer:

```
... CR LF SPC SPC SPC SPC SPC SPC SPC 3 0 0 0 0 CR LF ...  
... 13 10 32 32 32 32 32 32 51 48 48 48 48 13 10 ...
```

- You intercept the ciphertext

```
... 74 112 4 19 235 156 99 113 125 19 1 192 191 25 212 ...
```

Stream ciphers and message integrity

- Imagine you are able to intercept the bank transfer that puts your salary into your bank account, and that it is encrypted with a stream cipher, and not authenticated
- You know what your salary is, and in what position it is on the bank transfer:

```
... CR LF SPC SPC SPC SPC SPC SPC SPC 3 0 0 0 0 CR LF ...  
... 13 10 32 32 32 32 32 32 51 48 48 48 48 13 10 ...
```

- You intercept the ciphertext

```
... 74 112 4 19 235 156 99 113 125 19 1 192 191 25 212 ...
```

- The 19 in the ciphertext is at the same position as the first 48 in the cleartext

Stream ciphers and message integrity

- Imagine you are able to intercept the bank transfer that puts your salary into your bank account, and that it is encrypted with a stream cipher, and not authenticated
- You know what your salary is, and in what position it is on the bank transfer:

```
... CR LF SPC SPC SPC SPC SPC SPC 3  3  0  0  0 CR LF ...  
... 13 10 32 32 32 32 32 32 51 51 48 48 48 13 10 ...
```

- You intercept the ciphertext

```
... 74 112 4 19 235 156 99 113 125 16 1 192 191 25 212 ...
```

- Changing 19 to 16 in the ciphertext changes the first 48 to 51 in the received cleartext. No one will notice :)

Block ciphers

- Messages are treated in blocks of characters with fixed block size
- The key remains fixed for at least one session

Data Encryption Standard

↓

- There was a lot of controversy surrounding the S-box construction
- People were worried there were backdoors in the system
- But in the late eighties it was found that even small changes in the S-boxes gave a weaker system
- After the (re-)discovery of *differential cryptanalysis*, in 1994 IBM published the construction criteria

AES competition

- NIST put out a call for new algorithms in 1997, this was the start of the AES competition
- Requirements were: 128 bit blocks, 128, 192 and 256 bit keys, and that it should work well on several kinds of hardware and in software
- Five finalists
 - Rijndael (J. Daemen and V. Rijmen)
 - Serpent (R. Anderson, E. Biham, and L. Knudsen)
 - Twofish (B. Schneier, J. Kelsey, D. Whiting, D. Wagner, C. Hall, and N. Ferguson)
 - RC6 (RSA Labs)
 - MARS (IBM)

AES competition

- NIST put out a call for new algorithms in 1997, this was the start of the AES competition
- Requirements were: 128 bit blocks, 128, 192 and 256 bit keys, and that it should work well on several kinds of hardware and in software
- Five finalists
 - Rijndael (J. Daemen and V. Rijmen) ← AES (2000)
 - Serpent (R. Anderson, E. Biham, and L. Knudsen)
 - Twofish (B. Schneier, J. Kelsey, D. Whiting, D. Wagner, C. Hall, and N. Ferguson)
 - RC6 (RSA Labs)
 - MARS (IBM)

AES structure: 10, 12, or 14 rounds

Block ciphers

- Messages are treated in blocks of characters with fixed block size
- The key remains fixed for at least one session
- Direct use (“Electronic Code Book”) makes repeated plaintext blocks produce repeated cipher blocks
- Don't use ECB

Block cipher in Cipher Block Chaining mode

- Preserves data integrity
- Provides “diffusion”
- Feedback of previous cipher block

Symmetric key cryptography

In symmetric key systems, the encryption key is the same as the decryption key

Asymmetric key cryptography

In asymmetric key systems, the encryption key and the decryption key are different

Public key cryptography

The encryption key can be public, so that anyone can send secret messages to Bob

Public key cryptography

- Each user has a pair of keys, one public encryption key e , one secret decryption key d
- It is computationally hard to calculate d from e
- This is achieved by basing the algorithm on a difficult problem from number theory

MACs and digital signatures

- A Message Authentication Code is a “seal of authenticity” created in a symmetric key system
- If the same MAC can be created at the verifier, then the message hasn’t changed in transit
- Everyone that can check the MAC can create the MAC

MACs and digital signatures

- A Digital Signature is a “seal of authenticity” created in an asymmetric key system
- If the Digital Signature can be verified at the verifier, then the message hasn’t changed in transit
- Here, only Alice can sign

MACs and digital signatures

- In RSA, the secret “decryption” key now is the secret signing key, while the public “encryption” key now is the public verification key

One-way hash functions

- Large messages take time to MAC or sign
- A hash function creates an output that is much smaller than the message (or file)
- For any hash function, it should be easy to calculate $h(x)$ from x
- Then, it is easy to create MACs or digital signatures for $h(x)$
- A one-way function is one where it is easy to calculate $y = f(x)$, but computationally hard to calculate $x = f^{-1}(y)$

One-way hash functions

- A one-way function is one where it is easy to calculate $y = f(x)$, but computationally hard to calculate $x = f^{-1}(y)$
- But a hash function has output much shorter than the input
- There must be messages for which the output collides (so f^{-1} doesn't exist)
- “Collision resistant” does not mean that no two messages get the same hash value, it means it is hard to find two such messages
- As another example, hashing functions are often used to verify the integrity of files

One-way hash functions

- An example using the SHA-1 hashing algorithm

Standard algorithms?

- ISO does not standardize algorithms
- NIST (National Institute for Standards and Technology) does register standards for federal use in the US
- NIST standards and other well tested algorithms are used as some kinds of de facto standards
- Examples are DES, AES and the SHA family

De facto standard algorithms

- Stream ciphers: The A family in GSM and E family in Bluetooth
- Symmetric block ciphers: DES (56 bits), AES (128-256 bits), Blowfish, ...
- Asymmetric ciphers: RSA (any key size) and Elliptic Curve Cryptography (ECC, any key size), ...
- Cryptographic hashes: MD5 (128 bit hashes, weak), SHA-1 (160 bit hashes, deprecated), SHA-2 (224-512 bit hashes), SHA-3 (224-512 bit hashes, ?), ...

Key length

Table 7.1: Minimum symmetric key-size in bits for various attackers

Attacker	Budget	Hardware	Min security	(1996)
"Hacker"	0	PC	58	45
	< \$400	PC(s)/FPGA	63	50
	0	"Malware"	77	
Small organization	\$10k	PC(s)/FPGA	69	55
Medium organization	\$300k	FPGA/ASIC	69	60
Large organization	\$10M	FPGA/ASIC	78	70
Intelligence agency	\$300M	ASIC	84	75

From "ECRYPT II Yearly Report on Algorithms and Keysizes (2011-2012)"

Basic questions for crypto users

- Is the algorithm strong enough?
- Does the algorithm really work against my perceived threat?
- What about key management?
- What standard algorithm should I use?
- NEVER design a cryptosystem on your own
- Watch out for snake oil
